

# Ch 17. Temperature & Heat

## 17.1-3. Temperature

A measure of how hot /cold an object is

Temperature Scale

Celsius (centigrade)	°C
Fahrenheit	°F
Absolute (Kelvin, Scientific work)	K

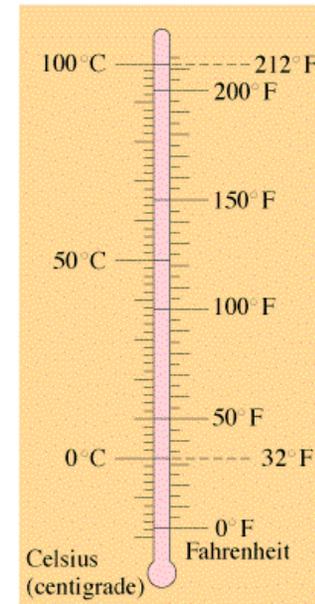

$\Delta T$  in C°, F°, or K

# Temperature Conversion

$$T_C = \frac{5}{9} (T_F - 32^\circ)$$

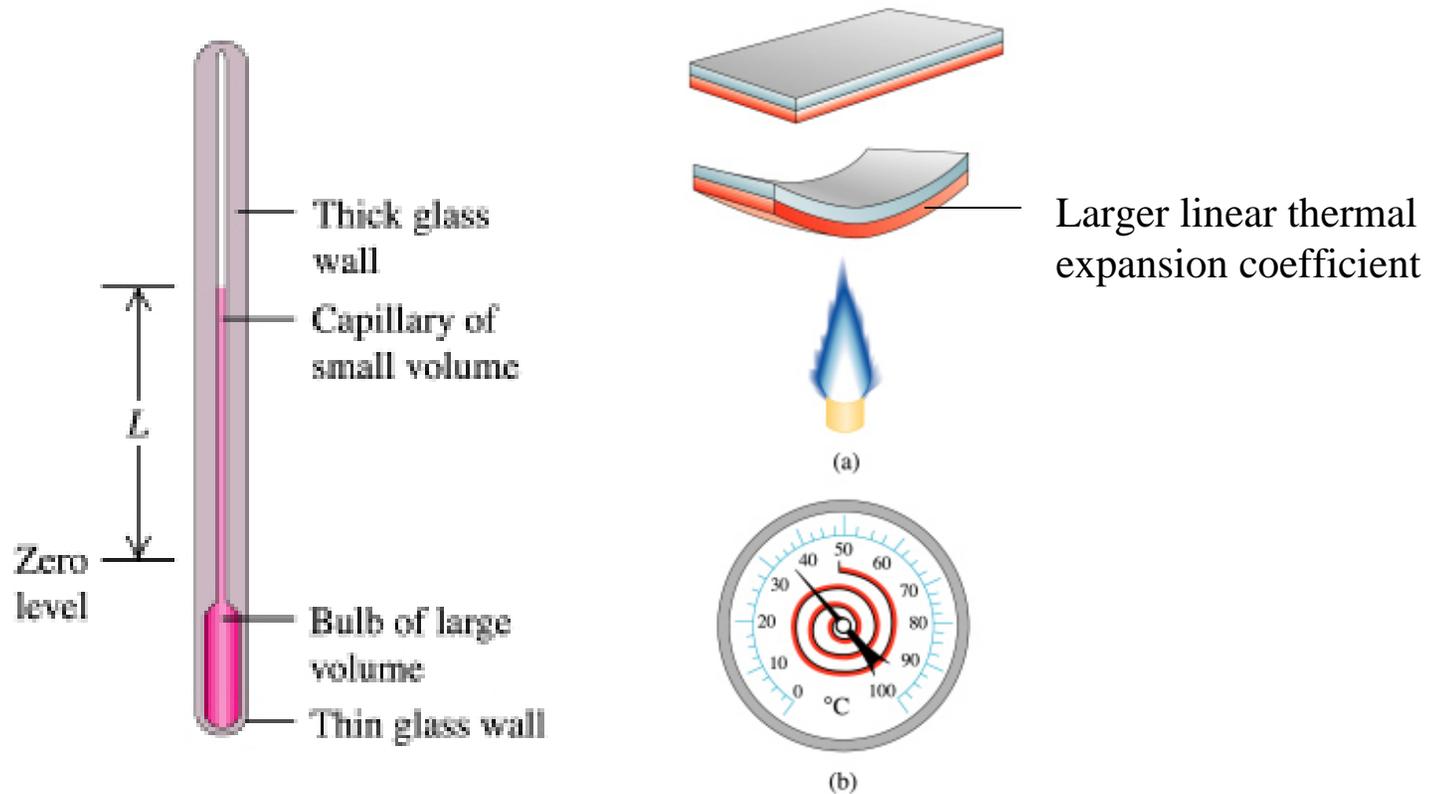

$$T_F = \frac{9}{5} T_C + 32^\circ$$

$$T_K = T_C + 273.15$$

	K	C	F
<u>Water boils</u>	373	100°	212°
	↑ 100 K	↑ 100 C°	↑ 180 F°
<u>Water freezes</u>	273	0°	32°
CO <sub>2</sub> solidifies	195	-78°	-109°
Oxygen liquifies	90	-183°	-298°
<u>Absolute zero</u>	0	-273°	-460°

# Thermometer

## 17-4. Thermal Expansion

**Most** substances:

Expand when heated

Contract when cooled

$$\frac{\Delta L}{L_0} = \alpha \Delta T \quad L = L_0 (1 + \alpha \Delta T)$$

$\alpha$  – Coefficient of linear expansion

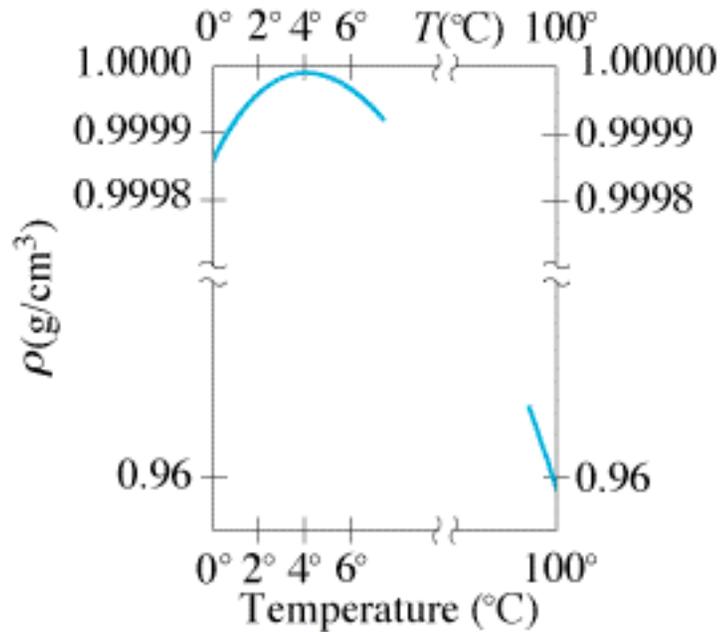

$$\frac{\Delta V}{V_0} = \beta \Delta T$$

$\beta$  – Coefficient of volume expansion

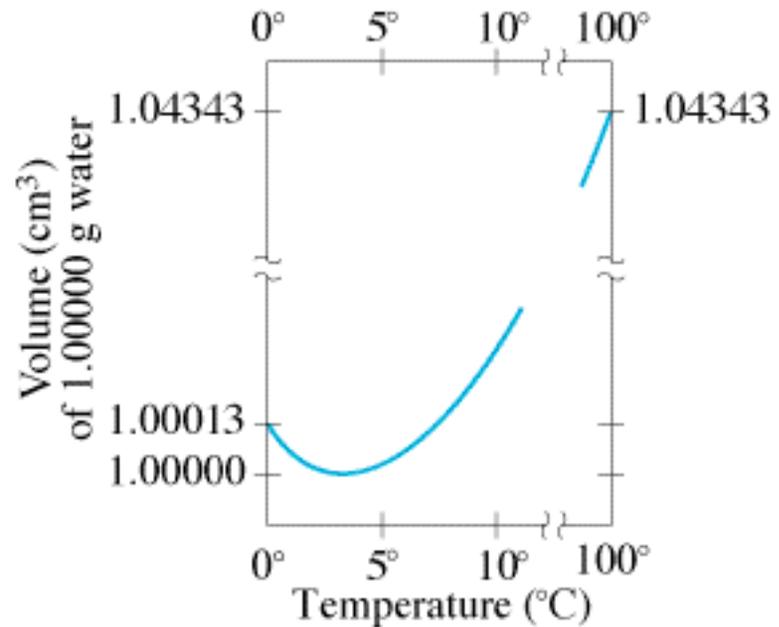

Glass,  $\beta \sim 10^{-5}/\text{C}^\circ$

Mercury,  $\beta \sim 10^{-4}/\text{C}^\circ$

# Anomalous Behavior of Water Below 4°C

(a)

(b)

Water expands as it cools from 4°C to 0°C, expands more upon freezing. In a pool of water, it freezes from **top**.

## 17-5. Quantity of Heat

Common units:

calorie (cal): amount of heat necessary to raise the temperature of  
1 gram of water by  $1\text{C}^\circ$

kilocalorie (kcal)  $1 \text{ kcal} = 1000 \text{ cal}$

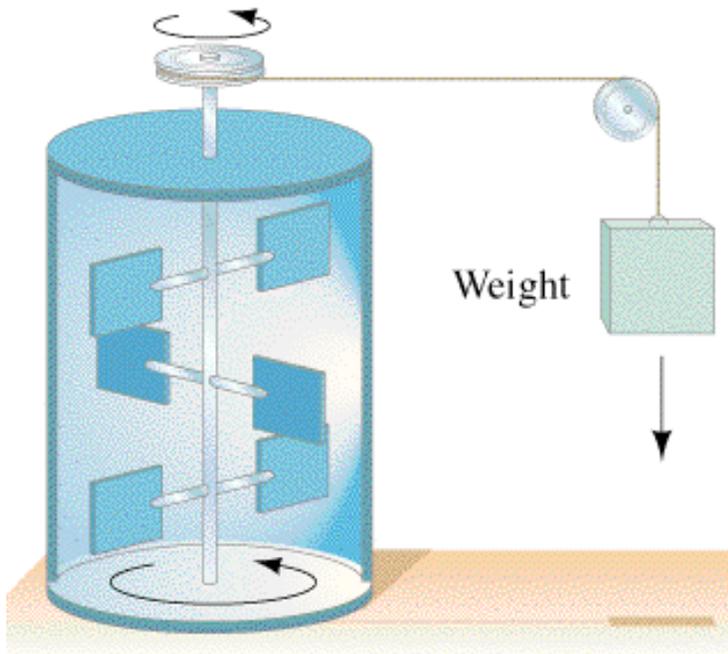

Calorie dietary usage,  $= 1 \text{ kcal}$

British thermal unit (btu)

amount of heat necessary to raise the temperature of  
1 lb of water by  $1\text{F}^\circ$

$1 \text{ btu} = 252 \text{ cal}$

# Mechanical Equivalent of Heat

$$4.186 \text{ J} = 1 \text{ cal}$$

Heat is **energy** that's **transferred** from one body to another because of a **difference in temperature**.

Like water, flows from high to low (temperature).

Not the energy a body contains.

# Specific Heat Capacity

Heat transfer  $Q=mc\Delta T$

Specific heat (capacity)  $c$ : J/kg-C° or J/kg-K

	kcal/kg -C°	J/kg -C
Water	1	4200
Wood	0.4	1700
Aluminum	0.22	900
Iron	0.11	450
Lead	0.031	130

# Molar Specific Heat

Unified atomic mass unit (u)

$^{12}\text{C}$  atom has exactly 12u

$$1\text{u} = 1.66 \times 10^{-27} \text{ kg}$$

Atomic / molecular mass

H atoms	1u	H <sub>2</sub> molecules	2u
N <sub>2</sub> molecules	28u	O <sub>2</sub> molecules	32u
CO <sub>2</sub> molecules	44u		

1 mole = amount of substance that contains as many atoms or molecules as there are in 12 grams of  $^{12}\text{C}$ .

Mole number

$$n = m/M$$

$$= \text{mass (gram)}/\text{Molecular mass (g/mol)}$$

In molar form:  $Q = mc\Delta T = nMc\Delta T = nC\Delta T$

Molar specific heat:  $C = Mc$

# Calorimetry

**Isolated system: Energy conserved**

Heat Lost = Heat Gain

Method 1: Keep heat positive

$$\Sigma m_i c_i \Delta T_i = \Sigma m_j c_j \Delta T_j$$

$$\text{Heat Gain} = mc(T_f - T_i)$$

$$\text{Heat lost} = mc(T_i - T_f)$$

Method 2: Keep sign consistent

$$\Sigma m_k c_k \Delta (T_f - T_i)_k = 0$$
